

# **String Manipulation**

**Programming I (PRG1)**

Diploma in Information Technology

Diploma in Financial Informatics

Diploma in Cybersecurity & Digital Forensics

Common ICT Programme

Year 1 (2019/20), Semester 1

# Objectives

At the end of this lecture, you will learn how to

- Access characters in strings
- How to manipulate strings

# Accessing Characters in Strings

- ❑ A **string** is a sequence of characters.

- ✓ Use the bracket operator **[ ]** to access a character in the string.

```
>>> name = 'Ngee Ann'  
>>> name[1]  
'g'
```

name	N	g	e	e		A	n	n
position	0	1	2	3	4	5	6	7

- ❑ Positions of a string's characters are numbered from 0, on the left, to the length of the string minus one.
- ✓ Use negative index to access characters from right to left.

```
>>> name[-1]  
'n'  
>>> name[-3]  
'A'
```

# String Slices

- A segment of a string is called a ***slice***.

- ✓ Use **[n:m]** operator to access part of the string from position n to m.

```
>>> name[0:4]  
'Ngee'
```

name	N	g	e	e		A	n	n
position	0	1	2	3	4	5	6	7

- ✓ If the first index is omitted, the slice starts from the beginning of the string.
- ✓ If the second index is omitted, the slice goes to the end of the string.

```
>>> name[:4]  
'Ngee'  
>>> name[5:]  
'Ann'
```

# Other String Operators

Operator	Description	Example <code>a='Hello'; b='Python'</code>
<b>+</b>	Concatenation - Adds values on either side of the operator	<b>a + b</b> Ans: <b>'HelloPython'</b>
<b>*</b>	Repetition - Creates new string, concatenating multiple copies of the same string	<b>a*2</b> Ans: <b>'HelloHello'</b>
<b>in</b>	Membership - Returns true if a character exists in the given string	<b>'H' in a</b> Ans: <b>True</b>
<b>not in</b>	Membership - Returns true if a character does not exist in the given string	<b>'M' not in a</b> Ans: <b>True</b>

# Built in String function

## ❑ len(word)

- ✓ Returns the length of the string

```
>>> len(name)  
8
```

name	N	g	e	e		A	n	n
position	0	1	2	3	4	5	6	7

# Built in String functions

Function	Description	Example
<b>capitalize()</b>	Returns a copy of the string with its first character capitalized and the rest lowercased.	<b>a.capitalize()</b> Ans: ' <b>Hello python</b> '
<b>lower()</b>	Converts all uppercase letters in string to lowercase	<b>a.lower()</b> Ans: ' <b>hello python</b> '
<b>upper()</b>	Converts all lowercase letters in string to uppercase	<b>a.upper()</b> Ans: ' <b>HELLO PYTHON</b> '
<b>find(str[, beg[, end]])</b>	Determine if str occurs in string or in a substring of string if starting index <u>beg</u> and ending index <u>end</u> are given. - Returns index if found and -1 otherwise	<b>a.find('on')</b> Ans: <b>10</b>  <b>a.find('ON')</b> Ans: <b>-1</b>

# Built in String methods

Function	Description	Example
<b>replace(old, new [, max])</b>	Replaces all occurrences of old in string with new or at most max occurrences if max given	<code>a='Hello Python'</code>
		<code>a.replace('o','z')</code> Answer: ' <b>Hellz Pythzn'</b>
<b>isalpha()</b>	Returns true if string has at least 1 character and all characters are alphabetic and false otherwise	<code>a.replace('o','z',1)</code> Answer: ' <b>Hellz Python'</b>
		<code>a.isalpha()</code> Answer: <b>False</b>
<b>isdigit()</b>	Returns true if string contains only digits and false otherwise	<code>a.isdigit()</code> Answer: <b>False</b>
<b>split()</b>	Splits the string into substrings if it finds instances of the separator	<code>a.split(" ")</code> Answer: <b>['Hello', 'Python']</b>

# Activity 1

- Given message = 'Welcome to ICT' , determine the output:

Python code	Output
>>> len(message)	
>>> message.find('ICT')	
>>> message.replace('ICT','NP')	
>>> message[10]	
>>> message[11:14]	
>>> 'NP' in message	
>>> message[22]	

# Activity 2

- ❑ Assume that string **s1** = 'Programming 1' & **s2** = 'PRG1', perform the following:

	Python code	Output
Determine the length of string <b>s1</b>	<code>&gt;&gt;&gt; len(s1)</code>	
Check if <b>s1</b> has even number of characters	<code>&gt;&gt;&gt; len(s)%2 == 0</code>	
Replace every character 'g' in string <b>s1</b> with character 'z'.	<code>&gt;&gt;&gt; s1.replace('g','z')</code>	
Append the string <b>s2</b> to the string <b>s1</b>	<code>&gt;&gt;&gt; s1 = s1 + ' ' + s2</code>	
Check if string <b>s1</b> starts and ends with the same character	<code>&gt;&gt;&gt; s1[0] == s1[-1]</code>	

# Activity 3

- ❑ Assume that string `s3 = '10;20;30'`, perform the following:

	Python code	Output
Splits the string <code>s3</code> into substrings using separator <code>'.'</code>	<code>&gt;&gt;&gt; s3.split()</code>	
Retrieve float value <code>'10'</code> from string <code>s3</code>	<code>&gt;&gt;&gt; index = s3.find(';')</code> <code>&gt;&gt;&gt; s3[0:index]</code>	
Retrieve value <code>'20'</code> from the string <code>s3</code>	<code>&gt;&gt;&gt; temp = s3[index+1:]</code> <code>&gt;&gt;&gt; temp[0:index]</code>	

# Activity 4 – DeleteString.py

## □ Write a Python program to

- ✓ Prompt user to input the original string and substring to delete
- ✓ Remove the first occurrence of the substring from the original string
- ✓ Display the modified string

```
Enter original string : To eat or not to eat
Substring to delete : or

The modified string is : To eat  not to eat
```
